Conditions of Use

The following conditions regulate the use of computer programs developed by the Hydrologic Engineering Center (HEC), Corps of Engineers, Department of the Army.

1. The computer programs are furnished by the Government and are accepted and used by the recipient individual or group entity with the express understanding that the United States Government makes no warranties, expressed or implied, concerning the accuracy, completeness, reliability, usability, or suitability for any particular purpose of the information or data contained in the programs, or furnished in connection therewith, and that the United States Government shall be under no liability whatsoever to any individual or group entity by reason of any use made thereof.
2. The programs belong to the United States Government. Therefore, the recipient agrees neither to assert any proprietary rights thereto nor to represent the programs to anyone as other than Government programs.
3. The recipient may impose fees on clients only for ordinary charges for applying and modifying these programs.
4. Should the recipient make any modifications to the program(s), the HEC must be informed as to the nature and extent of those modifications. Recipients who modify HEC computer programs assume all responsibility for problems arising from, or related to, those modifications. User support from the HEC to third party recipients will only be provided after the second party demonstrates that program difficulties were not caused by their modifications.
5. This "Conditions of Use" statement shall be furnished to all third parties that receive copies of HEC programs from the recipient. Third party recipients must be notified that they will not receive routine program updates, correction notices, and other program services from the HEC unless they obtain the program(s) directly from the HEC.
6. All documents and reports conveying information obtained as a result of the use of the program(s) by the recipient, or others, will acknowledge the Hydrologic Engineering Center, Corps of Engineers, Department of the Army, as the origin of the program(s).

MULTIPLE LINEAR REGRESSION
THE HYDROLOGIC ENGINEERING CENTER
GENERALIZED COMPUTER PROGRAM
704-G1-L2020

INTRODUCTION

1. ORIGIN OF PROGRAM

This program was developed in The Hydrologic Engineering Center by R. G. Willey and H. E. Kubik. A two-part FORTRAN II version was written in 1968; a September 1970 version was written in FORTRAN IV and included increased capability, and this version basically modifies the input to conform with present standards.

It is recognized that nearly all computer centers have access to multiple linear regression programs, but this program includes some different statistical philosophy and some capability that is particularly useful for regional analyses.

2. CAPABILITIES OF PROGRAM

The program makes a multiple linear regression analysis and has the following special features:

a. Automatic deletion. The analysis is first made with all of the specified independent variables and then the least significant variable is deleted and the analysis repeated.

b. Variable selection. All independent and dependent variables can be stored and then only those variables desired for a particular analysis may be used.

c. Combination of variables. New variables may be computed from the input variables, e.g., a parameter $A\sqrt{S}$ [basin area(A) times the square root of main channel slope (S)] can be computed when area and slope have been input.

d. Transformations. The variables may be transformed (square root, logarithmic or reciprocal) to more nearly linearize the relations.

e. Input regression parameters. The regression constant and regression coefficients may be input and the residuals (difference between observed and calculated), the adjusted multiple determination coefficient and the standard error of estimate will be computed.

3. HARDWARE AND SOFTWARE REQUIREMENTS

This program has been developed and tested primarily on the UNIVAC 1108 and the CDC 7600 computer. No tape units are required.

PROGRAM DESCRIPTION

4. PROGRAM ORGANIZATION

The program consists of a main program and two subroutines. Subroutine COMB is used to compute a new variable based on a combination of one or more variables. Subroutine CROUT solves a set of simultaneous equations to obtain the regression coefficients. The program will exit normally only in the main program. A macro-flow chart of the program organization is shown in figure 1.

5. THEORETICAL ASSUMPTION AND LIMITATIONS

The computations are made in accordance with the procedures given in "Statistical Methods in Hydrology" by Leo R. Beard, January 1962. The independent variables are deleted, in turn, based on the minimum adjusted partial determination coefficient (\bar{r}^2).

The adjusted multiple determination coefficient is used to compute the standard error of estimate. Care must be taken in insuring that there are more observations than variables. If the number of observations are very close to the number of variables, the results may be unreasonable.

Variables with zero or very little (.000001) variance are deleted from the analysis. A diagnostic is printed stating the name of the variable deleted because of this limitation.

6. METHODS OF COMPUTATION

The regression analysis is performed on either the transformed or non-transformed variables in a like manner. The basic equation is:

$$Y = a + \sum_{i=1}^n b_i X_i \quad (1)$$

where the X_i values are the independent variables and the Y value is the dependent variable. "n" is the number of independent variables in the analysis. The regression coefficients (b_i) are calculated using the Crout Method (Exhibit 1) for solution of the following equations:

$$\begin{aligned}
 \Sigma(x_1)^2 b_1 + \Sigma(x_1 x_2) b_2 + \dots + \Sigma(x_1 x_n) b_n &= \Sigma(yx_1) \\
 \Sigma(x_1 x_2) b_1 + \Sigma(x_2)^2 b_2 + \dots + \Sigma(x_2 x_n) b_n &= \Sigma(yx_2) \\
 \vdots & \\
 \Sigma(x_1 x_n) b_1 + \Sigma(x_2 x_n) b_2 + \dots + \Sigma(x_n)^2 b_n &= \Sigma(yx_n)
 \end{aligned} \tag{2}$$

where x_i is the deviation of the value X for variable i , the observation number being implied, from the mean (\bar{X}_i). $\Sigma(x_i)^2$ and $\Sigma(x_i x_j)$ can be determined from the following equations:

$$\Sigma(x_i)^2 = \Sigma(X_i - \bar{X}_i)^2 = \Sigma(X_i)^2 - (\Sigma X_i)^2/N \tag{3}$$

$$\Sigma(x_i x_j) = \Sigma(X_i - \bar{X}_i)(X_j - \bar{X}_j) = \Sigma(X_i X_j) - \Sigma X_i \Sigma X_j/N \tag{4}$$

where N is the number of events or observations.

The regression constant (a) is calculated by use of the equation:

$$a = \bar{Y} - \sum_{i=1}^n b_i \bar{X}_i \tag{5}$$

where \bar{Y} is the mean of the dependent variable for N events and the \bar{X}_i values are the means of each of the independent variables for N events.

The unadjusted (R^2) and the adjusted (\bar{R}^2) determination coefficients are determined by the following equations:

$$R^2 = \frac{b_1 \Sigma(yx_1) + b_2 \Sigma(yx_2) + \dots + b_n \Sigma(yx_n)}{\Sigma(y)^2} \tag{6}$$

$$\bar{R}^2 = 1 - (1 - R^2)(N - 1)/(N - NVAR) \quad (7)$$

where NVAR is total number of variables (both dependent and independent) in the analysis.

The partial determination coefficient for a variable is the percent increase in unexplained variance caused by deleting that variable from the regression equation. The adjusted partial determination coefficient is calculated by the following equation:

$$\bar{r}_{14.23}^2 = \frac{(1 - \bar{R}_{1.23}^2) - (1 - \bar{R}_{1.234}^2)}{1 - \bar{R}_{1.23}^2} \quad (8)$$

where the first subscript for the adjusted partial determination coefficient indicates the dependent variable, the second indicates the independent variable whose partial determination coefficient is being computed, and the subscripts after the decimal indicate the other independent variables involved in the computation.

The standard error of estimate (S_e) is calculated by the following equation:

$$S_e = \sqrt{(1 - \bar{R}^2) \sum (y)^2 / (N - 1)} = S_y \sqrt{1 - \bar{R}^2} \quad (9)$$

where S_y is the standard deviation of the dependent variable.

When the residual prediction option is specified the "RESIDUAL" column is calculated as the difference between the observed and predicted values. The "ERROR AS DEVIATE" column is calculated as the residual divided by the standard deviation. The "RATIO" column is calculated as the residual divided by the observed value.

EXHIBIT 1

Crout's Method*

One of the best methods for solving systems of linear equations on desk calculating machines was developed by P. D. Crout in 1941. This method is based on the elimination method, with the calculations arranged in systematic order so as to facilitate their accomplishment on a desk calculator. In this method the coefficients and constant terms of the equations are written in the form of a "matrix," which is a rectangular array of quantities arranged in rows and columns.

The method is best explained by an example. Suppose that in a multiple correlation analysis it is required to solve the following system of linear equations to obtain the unknown values of b_2 , b_3 , b_4 and b_5 .

$$\Sigma x_2^2 b_2 + \Sigma x_2 x_3 b_3 + \Sigma x_2 x_4 b_4 + \Sigma x_2 x_5 b_5 = \Sigma x_1 x_2$$

$$\Sigma x_2 x_3 b_2 + \Sigma x_3^2 b_3 + \Sigma x_3 x_4 b_4 + \Sigma x_3 x_5 b_5 = \Sigma x_1 x_3$$

$$\Sigma x_2 x_4 b_2 + \Sigma x_3 x_4 b_3 + \Sigma x_4^2 b_4 + \Sigma x_4 x_5 b_5 = \Sigma x_1 x_4$$

$$\Sigma x_2 x_5 b_2 + \Sigma x_3 x_5 b_3 + \Sigma x_4 x_5 b_4 + \Sigma x_5^2 b_5 = \Sigma x_1 x_5$$

For simplicity let us replace the coefficients of the b 's by the letters p , q , r and s , and the constant terms by the letter t , using subscripts 1, 2, 3 and 4 to denote the respective equations:

$$p_1 b_2 + q_1 b_3 + r_1 b_4 + s_1 b_5 = t_1$$

$$p_2 b_2 + q_2 b_3 + r_2 b_4 + s_2 b_5 = t_2$$

$$p_3 b_2 + q_3 b_3 + r_3 b_4 + s_3 b_5 = t_3$$

$$p_4 b_2 + q_4 b_3 + r_4 b_4 + s_4 b_5 = t_4$$

A continuous check on the computations as they progress may be obtained by adding to the matrix of the above system a column of u 's, such that $u = p + q + r + s + t$. The matrix and check column are written as follows:

* The Crout Method was presented at the AIEE Summer Convention in June 1941 by Prescott D. Crout. The method was developed by Gauss and refined by Doolittle.

$$\begin{vmatrix} p_1 & q_1 & r_1 & s_1 & t_1 & u_1 \\ & p_2 & q_2 & r_2 & s_2 & t_2 & u_2 \\ & & p_3 & q_3 & r_3 & s_3 & t_3 & u_3 \\ & & & p_4 & q_4 & r_4 & s_4 & t_4 & u_4 \end{vmatrix}$$

The elements p_1, q_2, r_3 and s_4 form the "principal diagonal" of the matrix. Examination of the original equations shows that the coefficients are symmetrical about the principal diagonal, i.e., $q_1 = p_2, r_1 = p_3, r_2 = q_3, s_1 = p_4, s_2 = q_4$, and $s_3 = r_4$.

This is characteristic of the system of equations to be solved in any multiple correlation analysis. Because of this symmetry, the computations are considerably simplified. While the Crout method may be used to solve any system of linear equations, the computational steps given here are applicable only to those with symmetrical coefficients.

The solution consists of two parts, viz., the computation of a "derived matrix" and the "back solution." Let the derived matrix be denoted as follows:

$$\begin{vmatrix} P_1 & Q_1 & R_1 & S_1 & T_1 & U_1 \\ & P_2 & Q_2 & R_2 & S_2 & T_2 & U_2 \\ & & P_3 & Q_3 & R_3 & S_3 & T_3 & U_3 \\ & & & P_4 & Q_4 & R_4 & S_4 & T_4 & U_4 \end{vmatrix}$$

The elements of the derived matrix are computed as follows:

$$P_1 = p_1 \quad P_2 = p_2 \quad P_3 = p_3 \quad P_4 = p_4$$

$$Q_1 = \frac{q_1}{p_1} \quad R_1 = \frac{r_1}{p_1} \quad S_1 = \frac{s_1}{p_1} \quad T_1 = \frac{t_1}{p_1} \quad U_1 = \frac{u_1}{p_1}$$

$$Q_2 = q_2 - P_2 Q_1 \quad Q_3 = q_3 - P_3 Q_1 \quad R_2 = \frac{Q_3}{Q_2}$$

$$Q_4 = q_4 - P_4 Q_1 \quad S_2 = \frac{Q_4}{Q_2} \quad T_2 = \frac{t_2 - T_1 P_2}{Q_2} \quad U_2 = \frac{u_2 - U_1 P_2}{Q_2}$$

$$R_3 = r_3 - Q_3 R_2 - P_3 R_1 \quad R_4 = r_4 - Q_4 R_2 - P_4 R_1 \quad S_3 = \frac{R_4}{R_3}$$

$$T_3 = \frac{t_3 - T_2 Q_3 - T_1 P_3}{R_3} \quad U_3 = \frac{u_3 - U_2 Q_3 - U_1 P_3}{R_3}$$

$$S_4 = s_4 - R_4 S_3 - Q_4 S_2 - P_4 S_1$$

$$T_4 = \frac{t_4 - T_3 R_4 - T_2 Q_4 - T_1 P_4}{S_4} \quad U_4 = \frac{u_4 - U_3 R_4 - U_2 Q_4 - U_1 P_4}{S_4}$$

The general pattern of the above computations, which may be applied to a system containing any number of equations, is as follows:

(1) The first column of the derived matrix is copied from the first column of the given matrix.

(2) The remaining elements in the first row of the derived matrix are computed by dividing the corresponding elements in the first row of the given matrix by the first element in that row.

(3) After completing the n^{th} row, the remaining elements in the $(n+1)^{\text{th}}$ column are computed. Such an element (X) equals the corresponding element of the given matrix minus the product of the element immediately to the left of (X) by the element immediately above the principal diagonal in the same column as (X), minus the product of the second element to the left of (X) by the second element above the principal diagonal in the same column as (X), etc. After each element below the principal diagonal is recorded, and while that element is still in the calculator, it is divided by the element of the principal diagonal which is in the same column. The quotient is the element whose location is symmetrical to (X) with respect to the principal diagonal.

(4) When the elements in the $(n+1)^{th}$ column and their symmetrical counterparts have been recorded, the $(n+1)^{th}$ row will be complete except for the last two elements, which are next computed. Such an element (X) equals the corresponding element of the given matrix minus the product of the element immediately above (X) by the element immediately to the left of the principal diagonal in the same row as (X), minus the product of the second element above (X) by the second element to the left of the principal diagonal in the same row as (X), etc., all divided by the element of the principal diagonal in the same row as (X).

The check column (U) of the derived matrix serves as a continuous check on the computations in that each element in the column equals one plus the sum of the elements in the same row to the right of the principal diagonal. That is,

$$U_1 = 1 + Q_1 + R_1 + S_1 + T_1$$

$$U_2 = 1 + R_2 + S_2 + T_2$$

$$U_3 = 1 + S_3 + T_3$$

$$U_4 = 1 + T_4$$

This check should be made after completing each row.

The elements of the derived matrix to the right of the principal diagonal form a system of equations which may now be used to compute the unknown values of b_2 , b_3 , b_4 and b_5 by successive substitution. This is known as the "back solution." The computations are as follows:

$$b_5 = T_4$$

$$b_4 = T_3 - S_3 b_5$$

$$b_3 = T_2 - S_2 b_5 - R_2 b_4$$

$$b_2 = T_1 - S_1 b_5 - R_1 b_4 - Q_1 b_3$$

It is very important that the computations be carried to a sufficient number of digits, both in computing the coefficients and constant terms of the original equations, and in computing the elements of the derived matrix. It is possible for relatively small errors in the coefficients and constant terms of the original equations to result in relatively large errors in the computed solutions of the unknowns. The

greatest source of error in computing the elements of the derived matrix arises from the loss of leading significant digits by subtraction. This must be guarded against and can be done by carrying the computations to more figures than the data. As a general rule, it is recommended that the coefficients and constant terms of the original equations be carried to a sufficient number of decimals to produce at least five significant digits in the smallest quantity, and that the elements of the derived matrix be carried to one more decimal than this, but to not less than six significant digits.

DESCRIPTION OF INPUT DATA
GENERALIZED COMPUTER PROGRAM
704-G1-L2020

T1, T2, T3 Title Cards

Three title cards for the identification of the output. A T1 must be in columns 1 and 2 of the first card. A new T3 card is required for each subsequent analysis which uses the same data set.

J1 - First Job Card

<u>Field</u> ⁽¹⁾	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1.	NVAL		Total number of values (variables) to be read for each observation and stored for use in this and subsequent analyses. This is not necessarily the number of variables to be included in the first analysis which will be specified by the TR card. Dimensioned for 18 variables.
2.	NCOMB		Number of new variables to be computed by combining two or more variables and constants. All combinations for subsequent analyses which use the same data must be performed in first analysis. Dimensioned for five combinations. Sum of NVAL and NCOMB must not exceed 18.
3.	IPRNT		Data list options.
		0	Provides list of input data for each job.
		1	Suppresses listing of input data.

⁽¹⁾ The standard card format for most HEC programs consists of columns 1 and 2 reserved for the card code (Field 0) and the remaining columns used for program specification or data. Columns 3-8 are Field 1 and the remaining 72 columns are divided into nine 8-column fields.

J1 Card (continued)

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
4.	IFRMT		Format of data on the cards.
		0	Data in standard format of (A2,A6,9F8.0) for card identification, observation identification, and data, respectively. The format for the second card, if required, is (8X,9F8.0).
		1	Special format will be read on FT card.
5.	IDELE		Deletion options.
		0	Automatic deletion of each variable with lowest partial determination coefficient, in turn, until only one independent variable remains.
		1	Suppresses automatic deletion.
6-10.			Not used.

NM - Variable Name Card

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>								
1.	DELTA		Increment which will be added to <u>all</u> data to meet certain constraints when logarithmic, square root, or reciprocal transformations are made. The increment should be zero unless the following constraints are violated: <table><tr><th><u>Transform</u></th><th><u>Constraint</u></th></tr><tr><td>Logarithmic</td><td>"data" + DELTA > 0</td></tr><tr><td>Square root</td><td>"data" + DELTA ≥ 0</td></tr><tr><td>Reciprocal</td><td>"data" + DELTA ≠ 0</td></tr></table>	<u>Transform</u>	<u>Constraint</u>	Logarithmic	"data" + DELTA > 0	Square root	"data" + DELTA ≥ 0	Reciprocal	"data" + DELTA ≠ 0
<u>Transform</u>	<u>Constraint</u>										
Logarithmic	"data" + DELTA > 0										
Square root	"data" + DELTA ≥ 0										
Reciprocal	"data" + DELTA ≠ 0										
2-10.	ANAMA		Alphanumeric name of each variable read in, NVAL (J1.1) names. Order must correspond to order of data as read. If more than one card is needed, the name for the 10th variable is placed in field 2 of the second card, etc.								

FT - Special Format Card

Supply this card only if IFRMT (J1.4) is positive.

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1-10.	IFMT		Format of data to be read from cards. The first field <u>must</u> read the data card code (the DT) in A2 format and the second field <u>must</u> provide for an alphanumeric identification of the observation in A format and NVAL (J1.1) floating point fields, e.g., (A2, A4, 10X, 10F6.0). The second A field cannot exceed six columns. <u>NOTE:</u> Parentheses must be provided in specification.

CJ - Combination Job Card⁽¹⁾

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1.	NOP		Number of operation codes necessary to compute a new variable by combining one or more variables. Dimensioned for 20 operation codes.
2.	NCØN		Number of constants necessary to compute a new variable. Dimensioned for five constants.
3.	ANAMA		Alphanumeric name of new variable being computed.
4-10.			Not used.

C0 - Combination Operations Card⁽¹⁾

Supply this card only in conjunction with CJ card.

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1-10.	IOP		Operation to be performed, NOP (CJ.1) values.

⁽¹⁾ Provide NCOMB (J1.2) sets of CJ, C0, and, if required, CC cards.

C0 Card (continued)

The sequence of operations necessary to obtain a desired computed variable must be specified by "operation codes." These operations are performed by using three operating registers, argument (ARG), accumulator (ACC) and storage (STORE). The accumulator has been initialized to zero prior to computations. Any constants necessary for the arithmetic will be entered on the CC card in the sequence necessary. The final value in the accumulator is used as the value for the new variable.

Operation		Operation Code
Variable→ARG	-vn	Variable number, preceded by minus sign, to use next where "vn" is order number as read in or combined. This variable becomes the argument.
ARG+ACC→ACC	1	Add argument to accumulator.
ACC-ARG→ACC	2	Subtract argument from accumulator.
ARG(ACC)→ACC	3	Multiply argument times accumulator.
ACC/ARG→ACC	4	Divide accumulator by argument.
ACC ^{ARG} →ACC	5	Raise accumulator to power of argument.
ACC→STORE then 0.→ACC	6	Store accumulator while further arithmetic is done. Accumulator is then reset to zero.
STORE→ARG	7	Retrieve stored value. This value now becomes the argument.
Constant→ARG	8	Use the next constant on the CC card as the argument.

CC - Combination Constants Card⁽¹⁾

Supply this card only if NCON (CJ.2) is positive.

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1-5.	CNST		Supply NCON (CJ.2) values.
6-10.			Not used.

⁽¹⁾ Provide NCOMB (J1.2) sets of CJ, C0, and, if required, CC cards.

TR - Analysis Specification Card

This card is provided for each analysis.

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1.	IDEP		Number identifying the order number of the dependent variable in the total array of values read in, i.e., 3 if third value in the array is the desired dependent variable.
2-6.	IFUNC		Variable deletion or transformation code for each variable. NVAL (J1.1) plus NCOMB (J1.2) values in special (I2) format, i.e., the code for the first variable read would be in column 10, the code for the second variable in column 12, etc.
			Operation
		0	Delete from current analysis
		1	No transformation
		2	Square root
		3	Logarithmic, base 10
		4	Reciprocal
7.	NOBR		The number of observations to be used in this analysis. The program will count the number of observations (NOBS) as the data are read; therefore, may be left blank if all observations are to be used in analysis. If positive, the first NOBR observations will be used, but must be less than or equal to NOBS. Dimensioned for 500 observations.
8.	IRES		Residual-prediction options. Provides a tabulation of the observed, calculated, the difference between the observed and calculated, and, if the log transformation of the dependent variable, the ratio of the observed to the calculated. The computation for a multiple linear regression analysis will be performed when $IRES \geq 0$. Predetermined regression parameters will be read (RP card) when $IRES = -1$.

TR Card (continued)

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
		-1	Regression parameters to be read in with <u>no</u> analyses.
		0	Suppresses residual--prediction routine.
		>0	Positive number indicating maximum number of independent variables to be included in equation. Routine will operate for each deletion thereafter.
9-10.			Not used.

RP - Regression Parameters Card

Supply this card only if IRES (TR.8) is -1.

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1.	AA		Regression constant.
2.	BB		Regression coefficients. Supply same number of coefficients as there are independent variables (one less than the number of IFUNC (TR.2) values that are greater than zero) in the order corresponding to data.

DT - Input Data Cards

Input data need only be provided for first analysis. Subsequent analyses can use same data provided all necessary data are read in first analysis. The data may be in the following format or the format specified by the FT card. Dimensioned for 500 observations.

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1.	XID		An alphanumeric identification for the observation.
2.	X		Value for the first variable.

DT Card (continued)

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
3-10.	X		Value for succeeding variables, NVAL (J1.1) values. If more than one card is needed, the value for the 10th variable is placed in field 2 of the second card, etc. The identification (XID) can be repeated in field 1 to assist in identifying each card.

ED - End of Data Card

Supply the same number of ED cards as required to supply one observation on DT cards.

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
0.	ID		The letters ED <u>must</u> appear in columns 1 and 2.
1-10.			Not used.

NJ - Next Job Card

<u>Field</u>	<u>Variable</u>	<u>Value</u>	<u>Description</u>
1.	NEXT		This variable indicates what type of job follows according to the following values:
		0	Begin a new job. Branches to beginning of program and reads T1, T2, and T3 cards for a new job or for a normal stop.
		1	Different analysis with same input data. Branches to read T3, TR, and, if required, RP cards. (No data cards provided.)

T1 card, plus three blank cards, will cause a normal STOP.
